Abstract

The efficiency of telecommunication systems including a switch and a memory for storing messages originating from a first terminal and destined for a second terminal, can be increased by introducing a generator in the second terminal for generating a specific signal to be sent to the switch and defining a user of the second terminal being interested in a specific message mail, and by providing the switch with a detector for detecting the specific signal and with a processor for in response to the detecting ordering the memory to generate the specific message to be sent to the second terminal. By introducing a further generator in the first terminal for generating an indication signal to be sent to the switch and defining a message originating from a user of the first terminal being a specific message, the telecommunication system offers many user possibilities.
